Mid-Michigan Macroinvertebrates Identification Guide & Descriptions

Mayfly
Nymphs have 3 tail filaments – occasionally 2 tail filaments – never paddle or fan-like
Feathery gills line the sides of the abdomen on nymph
Color of nymph can be green brown, gray but usually black

Caddisfly
Larvae are usually cylindrical and “C” shaped
Some larvae are free-living (collector-filterers)
Others are case makers (shedders-detritivores & shedders-herbivores)

Stonfly

Gilled Snails
- Have gills for breathing
- Soft body inside a hard, spiral shaped shell
- Plate-like door (called the operculum) protects the opening of the shell
- Shells usually open on the right side
**Dobsonfly (Hellgrammite)**
- Includes some of the largest larvae
- Larvae are carnivorous predators and may bite – mouth has large chewing pinchers
- Larvae have 3 pr. of well-developed legs on the thorax
- Larva has many fleshy, filamentous lateral appendages on each side of the abdomen
- Gill tufts on the underside of the tail of larvae
- Abdomen of larvae ends in a pair of short spiny prologs each with 2 hooks

**Alderfly**
- Similar to a dobsonfly
- Usually smaller than a dobsonfly larva
- Larvae has a prominent, single tail

**Water Penny (beetle larva)**
- The water penny is the aquatic larva of a beetle
- The body is often stuck flat to surfaces as rocks and other flat substrates and looks like a tiny round leaf
- Larva is green, brown, black, or tan
- Segmented plate-like covering on larva
- Six tiny segmented legs beneath the round body
**Damselfly**
- Nymphs have slender bodies with 3 long tail-like gills
- Nymphs have no abdominal gills and tail supplemental gills are paddle-shaped
- Long legs are close to the head
- Large compound eyes and extendable jaws fold under the head – very good vision
- Nymphs are grey, grey or brown in color
- Nymphs found among stones and in leaf litter at bottom
- Nymphs are predators and feed on other macroinvertebrates in the water – may also be cannibals eating each other

![Damselfly Image]

**Dragonfly**
- Most nymphs have oval and flattened robust, elongated bodies or spider-like bodies –
- Nymphs are usually grey, brown or green
- Nymphs have large eyes, are predators with distinct mouthparts used to capture prey
- 6 legs and a pair of small wings may be seen developing on the back

![Dragonfly Image]

**Aquatic sowbug**
- Have 7 pr. of legs, 2 pr. antennae – one much longer than the other
- Similar in appearance to terrestrial sowbugs or “roly-polys”

![Aquatic Sowbug Image]
**Scuds**
- Sometimes called freshwater shrimp
- Are laterally compressed – side swimmers

**Cranefly**
- Larvae are worm-like with thick skinned segmented body – somewhat transparent with digestive tract visible- may be greenish or grayish
- Larvae are rounded at one end and disc like spiracles at the other end

**Midge**
- Larvae are cylindrical, thin, soft, and often curled with anterior and posterior prologs and hardened head capsule
- Larvae burrow in the mud and use salivary secretions to bind substrate particles into tubes or tunnels in which they live
- Larvae feed on suspended matter in water and organic matter in the mud - gathering collector
- After the first molt, most midges take on a pink color then turn into a deep red “called blood-midges or blood worms, found in low oxygen conditions (See blood midge)
**Blackfly**
- Larvae have brush-like mouth part that collect tiny organisms or organic matter like a sieve out of water – collectors/filterers
- Larvae tend to stay attached to substrate by producing a silk thread to adhere- tiny hooks on the abdomen help to attach

![larvae](image)

**Leeches**
- Segmented, flattened and a sucker on both ends of the body
- Tan to brown in color
- Can be carnivores, detritivores, but mostly external parasites
**Air Breathing Snail**
- Left opening with no plate-like covering (operculum) over opening
- Respire via lungs so they are not dependent on dissolved oxygen in the water
- Found grazing on a variety of substrates
- Grazers

**Cranefly**
- Diptera (true fly)
- Often black/grey in color

**Blood midge**

**Giant Water Bug**
Back Swimmer

- Swims on its back paddling with long fringed hind legs
- Back is convex with wings white or lightly colored with cross striations – can have green, brown or yellowish color (wings are lighter than the body area)
- Nymphs of water bugs molt several times before reaching adult
- Nymphs receive oxygen through their skin in pockets at the tip of the abdomen
- Adults breath air from the surface of the water
- Nymphs and adults are predators and attack prey as aquatic insects up to large as tadpoles and small fish
- Can inflict painful bite even to humans

Water Boatman
